Dynamic relationships between oil revenues, government spending and economic growth in an oil-dependent economy

Helmi Hamdi a,⁎, Rashid Sbia b

1. Introduction

Is natural resource-rich a blessing or a curse for a country? This question has generated considerable academic work. Even though, with an extensive literature, a convincing answer is not provided. Furthermore, the relationship between natural resource abundance and economic growth is controversial among scholars. It could not be settled among economists that natural resource abundance is either a curse or a blessing for natural resource-rich countries.

The first body of the literature establishes a negative relationship between resource abundance and poor economic performance (Auty (1986, 1990, 1993, 1998, 2001), Bulmer-Thomas (1994), Gelb (1988), Lal and Myint (1996), Ranis (1991), Sachs and Warner (1995, 1997, 1999)). The results appear to support the “resource curse” hypothesis, Sachs and Warner (1997) find a clear negative relationship between natural resource based exports (agriculture, minerals and fuels) and growth in the period 1970–90 from a sample of 95 developing countries. Two exceptions were Malaysia and Mauritius that sustained 2% per year growth during 1970–80. In the same way, Auty (2001) found that per capita income of resource poor countries grew between two to three times faster than that of the resource-abundant countries for the period 1960–1990. He admits that crop-led resource abundance would be expected to have lower growth compared to its manufacturing equivalent. Furthermore, mineral driven countries have been among the weakest performers. This so-called “resource curse” has inspired many economists to explain its origins.

Nevertheless, such conclusions exposed above are not without criticism. The results are very sensitive to the period chosen, to the definition of “natural resources” and to the methodology used. Some scholars put forward some doubts about the robustness of these findings due to differences in the measurements of natural resources abundance (Stijns, 2005). Schrank (2004) explains that this evidence does not prove that natural resources abundance of any kind causes poor economic growth even if they are correlated. Correlation does not mean causation. This is what we read in every econometrics manual. Ross (2003) goes further and put forward that the relationship between natural resources abundance and poor economies may be completely spurious by omitting a third variable.

As in most natural resource-rich countries, Bahrain’s economic growth has been strongly influenced by the volatility of oil, gas and mineral prices in international markets. This reveals Bahrain’s economic dependence on its oil sector even though it is considered as
the least oil dependent compared to its regional peers. Bahraini growth rates have generally followed a similar path to Saudi growth rates but have been less volatile because of huge gaps in oil and gas production and reserve between the two countries.

Bahrain became one of the first Gulf countries to start diversifying its economy. In the late 70s, the government went one step further in its diversification policy by attracting financial and service institutions to set up regional offices in the country. Moreover, Bahrain was among the first countries in the Middle East and North Africa region to build an industrial base and it has been the most attractive for foreign investors, including regional ones in its industrial development (Looney, 1989). During the past decades, the government has intensified the structural reforms to improve the infrastructure of the kingdom as well as the well being of Bahraini citizens. Bahrain has become an open-ended economy with liberalized trade and capital account. It has also become the hub of international affairs and the preferred destination for investors.1 Quickly, Bahrain emerged as a key player for banking, Islamic finance, Islamic insurance industry, transportation and communication in the Gulf region and has become home to many multinational firms. Nowadays, the economy has known an unprecedented dynamism, population has been growing drastically and projects have been multiplying. The goal of the Bahraini government in development plans was to reduce the dependence of current expenditures to oil revenues, financing these costs through non-oil sources.

Nevertheless, the slow-down in economic activity between the 1990s and 2000s has caused severe fiscal imbalances for Bahrain and oil revenues decreased drastically.2 During the last decade, the situation has worsened as the world economy has known a period of severe volatility in oil prices.3 As a result, Bahrain’s fiscal position moved from a minor deficit in 2002 (~0.1% of GDP) to a greater deficit of about 10% of GDP in 2009 due to the drop in oil revenues. Total revenue increased from BD 1.04 billion in 2000 to BD 2.8 billion in 2008 before decreasing to BD 1.7 billion in 2009 (Central Informatics Organisation, 2011). Oil and gas revenues registered a growth from BD 765 million in 2000 to BD 2.3 billion in 2008 before decreasing to BD 1.4 billion in 2009, while non-oil revenues rose from BD 264 million in 2000 to BD 367 million in 2008 before going back BD 262 million in 2009 (Central Informatics Organisation, 2011). This means that the government revenues and the overall fiscal policy in the Kingdom remain hugely based on oil revenues. Oil revenues are the life blood of the Bahraini economy (Hamdi and Sbia, 2013a,b).

Regardless of oil revenue volatility, the government has always kept a high level of current expenditures. By contrast, capital or development expenditures are sensitive to fluctuation in oil revenues. These simple and general observations show the vulnerability of the government fiscal situation to unexpected oil revenue shocks. Government cannot adjust its current spending easily in the case of a negative oil market. In this condition, when oil prices go down, the government is not able to reduce the size of its activities immediately, leading to a significant budget deficit (Farzanegan, 2011). This makes budget deficits a critical issue for the government. It is then important to consider a reform of the tax system more seriously.

Given the weight of oil in the small kingdom, this paper sheds light on the importance of oil revenues in the Kingdom of Bahrain. To the best of our knowledge, this type of question has never been analyzed in modern literature despite the importance of oil in financing the economies of oil-dependent countries.4 Therefore, this paper is the first attempt in literature to analyze the short-run and long-run relationships between oil revenues, government expenditures and economic growth in the case of an oil-dependent economy. To reach this goal, we use an econometric model based on cointegration and error correction model techniques for a long time series data which covers the period from 1960 to 2010. Overall results suggest that despite the efforts of the Bahraini government to diversify its economy, oil revenues remain the principal source for growth and the main channel that finance government spending as they represent 87.85% of total government revenues in 2011 (Central Informatics Organisation, 2011). Therefore, we encourage the government of Bahrain to continue working on effective growth-oriented strategies and to undertake more structural reforms to promote non-oil sector.

The remainder of the paper is organized as follows: Section 2 provides a theoretical background on the macroeconomic consequences of oil price volatility. Section 3 presents the econometric methodology; Section 4 provides the results while Section 5 concludes.

2. Macroeconomic consequences of oil volatility

Last century, especially post-World-War-II period, has witnessed multiple oil shocks including Suez Crisis of 1956–57, the Arab oil embargo of 1973–74, the two oil shocks (1973–79), the Iranian revolution of 1978–79, the Iran–Iraq War in 80s, the Gulf War in 1990–91, and recently the spike in oil prices in 2007–2008 and 2011.5 Consequently, economists have attempted to provide arguments to explain the behavior of oil prices and to assess the impact of oil shocks on various economies shedding light on different channels of transmission. Broadly, the behavior of oil prices has been investigated through three main approaches: the economics of exhaustible resources, the supply–demand framework and the informal approach (Fattouh, 2007). These studies were initiated by the pioneering works of Mork and Hall (1980), Sachs (1981), Darby (1982) and Hamilton (1983).

The study of Mork and Hall (1980) constructed and simulated a small macroeconomic model of the United States with energy. Their results reveal that large and unanticipated changes in the price of energy have significant negative effects on the economy. They concluded that oil price shock was a major cause of the 1974–75 recession and inflation. Moreover, they extend the analysis by explaining the role of other factors as the removal of the last price controls of the Economic Stabilization Program, and the slowdown of investment activity. Sachs (1981) explained that oil price peak (1973–74) generated considerable surplus in OPEC countries while it led to alarming deficits in both developed and developing countries. Further, income and consumption were deeply impacted. Darby (1982) conducted tests of the significance of oil-price variables in extended Lucas–Barro real income equations of oil-price variables for different countries including the United States, the United Kingdom, France Canada, Germany, Italy, the Netherlands and Japan. However, he could not establish a substantial relationship between oil prices and macroeconomic variables. Hamilton (1983) analyzed the influence of the oil price boom on the U.S. output. Hamilton’s paper is considered as an important turning point in oil–macro research. It revealed the strong relationship between oil price shocks and U.S. recessions in a clear manner. These results were confirmed later on by Hooker (2002), Hamilton (2003) and

---

1 It is worth recalling that in Bahrain there are no taxes imposed on personal income, wealth or capital gains. Furthermore, there are no death duty taxes or inheritance taxes.
2 This is mainly due to the Gulf wars and the Asian crisis. South Asian countries are the most important trade partners of Bahrain.
4 The paper of Fasano and Wang (2001) is the only available work that analyzes the relationship between fiscal expenditure policy and non-oil real GDP growth in member countries of the Gulf Cooperation Council (GCC). Their model comprises of the three following variables: capital expenditure, recurrent expenditure and GDP.
5 Hamilton (2011) provides a brilliant survey of oil shocks since 1859 with a particular focus on the events associated with significant changes in oil price.
Jiménez-Rodríguez and Sánchez (2005). Further, Hamilton (1983) applies in his analysis a vector autoregressive (VAR) model that was newly introduced by Sims (1980). This method became a standard tool for empirical studies investigating the impact of oil price on macroeconomic aggregates.

For a long time, the related literature on the impact of oil price shocks on macroeconomic aggregates was mainly focused on oil-importing in developed countries and specifically in the United States (Bruno and Sachs 1982), Burbidge and Harrison (1984), Mork et al. (1994), Levin and Loungani (1996), Papapetrou (2001), Balke et al. (2002), Bollino (2007) and Cooper (2003) are among others), Jones and Leiby (1996) and later Jones et al. (2004) provided an extended survey of the evolution of the oil price–macroeconomics nexus in developed countries. With less extent, some recent academic works explored the relationship between oil prices and macroeconomics in oil-importing developing countries. Some examples are Ragunidin and Reyes (2005) for Philippine, Rafiq et al. (2009) for Thailand, Rafik and Sonia (2009), Jbir and Zouari-Ghorbel (2009) for Tunisia, Jbir and Zouari-Ghorbel (2010) for Morocco, Ozlale and Pekkurnaz (2010) for Turkey and Malik (2010) for Pakistan.

Recent literature on oil shocks also treated the impact of oil prices on macroeconomics aggregate in oil-exporting countries. For example, Eltony and Al-Awadi (2001) claimed that symmetric oil price shocks play a key role in clarifying macroeconomic variables’ behavior in Kuwait. Their analysis demonstrated the sensitivity of government expenditures to oil price shocks in oil-dependent country. Ayadi (2005) investigated the relationship between oil price changes and economic development in Nigeria through industrial production. He found that oil price changes have only indirect effect on industrial production. Thus, he concluded that this relationship is insignificant. Similarly, Olomola and Adejumo (2006) examined the effects of oil price shocks on output, inflation, real exchange rate and money supply in Nigeria. Comparing to Ayadi (2005) who used annual data, Olomola and Adejumo (2006) used quarterly data from 1970 to 2003. They suggested that oil price shocks have a significant impact on money supply in the long-run. Further, Akpan (2009) scrutinized the asymmetric effects of oil price shocks on the Nigerian economy. The empirical results revealed a strong positive relationship between positive oil price changes and real government expenditure. Moreover, oil price shocks have marginal effects on industrial output. These results confirmed Ayadi (2005) and Olomola and Adejumo (2006) conclusions about Dutch disease syndrome in Nigeria. Mehrara (2008) explored asymmetric relationship between oil revenues and output growth for 13 oil-exporting countries. He found that gross domestic output reacts in an asymmetric or non-linear way to oil revenues shocks. From a magnitude point of view, he stated that the magnitude of negative oil price shock on GDP is larger than a positive oil price shock. In a VAR framework, Farzanegan and Markwardt (2009) considered the dynamic relationship between oil price shocks and major macroeconomic variables in Iran. They point out the asymmetric effects of oil price shocks. They found that positive as well as negative oil price shocks expressively raise inflation. Moreover, positive relationship between positive oil price changes and industrial output growth was found. They confirmed through their results the “Dutch Disease” hypothesis with abnormal real effective exchange rate appreciation. Berument and Ceylan (2010) evaluated the impact of oil price shocks on the economic growth in selected MENA countries. Their estimates suggested that oil price increases have a statistically significant and positive effect on output in Algeria, Iran, Iraq, Kuwait, Libya, Oman, Qatar, Syria and the UAE. While the impact of oil price increases has no significant impact on output in Bahrain, Djibouti, Egypt, Israel, Jordan, Marroco and Tunisia. The recent study of Farzanegan (2011) analyzed the dynamic effects of oil shocks on disaggregated expenditures of the Iranian government for the period 1959 to 2007. Empirical results show that Iran’s military and security expenditures respond considerably to a shock in oil revenue (or oil price). However, social spending components did not. Bouchaour and Al-Zeaud (2012) investigated the impact of oil price distortion on Algerian macroeconomics during the period 1980 to 2011. Using a Vector Error Correction Model (VECM), their results reveal that oil prices have a minor impact on the most variables in the short term excluding inflation and real effective exchange rate. While in the long run, oil prices have a positive impact on real gross domestic product and inflation. Further oil prices have a negative impact on real effective exchange rate and unemployment.

3. The econometric methodology

3.1. Data

The data frequency is annually, and the observation spans are from 1960 to 2010 of the following three variables: oil revenues, total government spending and economic growth. Firstly, oil revenues are the rents from oil and gas in real term. These rents are the main source of income of the government of Bahrain and they represent 22.7% of GDP and 87.85% of government revenues in 2011 (Central Informatics Organisation, 2011). Therefore, oil revenues are also the central source of government expenditures. This means that in the case of increasing oil revenues, the government expenditures also go up because of the larger size of government (Farzanegan, 2011). Whereas, when oil prices fall, the government expenditures would also shrink and in some cases it can cause a significant budget deficit.

Secondly, the second variable is total real government spending in real term. In Bahrain, government spending consists of the combined current and capital spending of central government including debt interest. The current expenditures are recurring; they intend to maintain the present capacities of government administration. They include final consumption expenditure, property income paid, subsidies and other current transfers (e.g., social security, social assistance, pensions and other welfare benefits). By contrast, capital expenditure is spending on assets. It is the purchase of items that will last and will be used time and time again in the provision of a good or service. Examples would be the building of a new school, the purchase of new equipment, building new roads and so on.

Finally, the third variable is economic growth and it is proxied by gross domestic product (GDP).

All variables are in real local currency and they are also in logarithmic form. Data are collected from various sources such as the World Bank (2012) and the Bahrain Ministry of Finance and National Economy (1991).5

Fig. 1 illustrates the trajectory of oil revenues, government spending and economic growth during the period of our study. Oil revenues increased significantly since 1960, this is due to the increase in oil prices and the high demand for oil and energy. As a result, the increase in oil revenues allows the Bahraini government to invest and to improve the infrastructure of the small kingdom. From Fig. 1, we can clearly see the trajectory of GDP which follows the revenues of oil. Therefore, we can conclude that when oil revenues increase, government expenditures increase which in turn improve the economic growth. The positive relationship between the three indicators

5 Data from WDI and IFS are available from 1970 while data from the Bahrain Ministry of Finance and National Economy (1991) start from 1960. Therefore, we completed the published data from WDI and our study covers the period from 1960 to 2010. The aim is to have a long time series data and efficient results. Data is available upon request.
started in 1973 following the oil shock, where the prices of oil reached a record.

3.2. Methodology

Our empirical investigation has two objectives. The first is to examine the long-run relationship between GDP, government expenditures and oil revenues, while the second is to examine the short-run relationship between the variables. The basic testing procedure requires three steps. The first step is to test whether the variables contain a unit root to confirm the stationarity of each variable (Engle and Yoo, 1987). This is done by using the Augmented Dickey–Fuller tests (F-ADF) and Philips–Perron (PP) tests (1998). The second step is to test whether there is a long-run cointegrating relationship between the variables. This is done by the use of the Johansen–Fisher methods. Finally, if all variables are I(1) (integrated of order one) and cointegrated, short-run elasticities can be computed using the vector error correction model (VECM) method suggested by Engle and Yoo (1987). In this case, an error correction mechanism exists by which changes in the dependent variables are modeled as a function of the level of the disequilibrium in the cointegrating relationship, captured by the error-correction term (ECT), as well as changes in the other explanatory variables to capture all short-term relations among variables (Pao and Tsai, 2010). The VECM in four variables case can be written as follows:

\[ \Delta \text{LGDP}_t = \alpha_1 + \sum_{i=1}^{p} \beta_{1i} \Delta \text{LGDP}_{t-i} + \sum_{i=1}^{q} \beta_{1i} \Delta \text{LOILR}_{t-i} + \sum_{i=1}^{r} \beta_{1i} \Delta \text{LTEX}_{t-i} \]

\[ + \lambda_1 \text{ECT}_{t-1} + \mu_{1t} \]  

(1)

\[ \Delta \text{LOILR}_t = \alpha_2 + \sum_{i=1}^{p} \beta_{2i} \Delta \text{LGDP}_{t-i} + \sum_{i=1}^{q} \beta_{2i} \Delta \text{LOILR}_{t-i} + \sum_{i=1}^{r} \beta_{2i} \Delta \text{LTEX}_{t-i} \]

\[ + \lambda_2 \text{ECT}_{t-1} + \mu_{2t} \]  

(2)

\[ \Delta \text{LTEX}_t = \alpha_3 + \sum_{i=1}^{p} \beta_{3i} \Delta \text{LGDP}_{t-i} + \sum_{i=1}^{q} \beta_{3i} \Delta \text{LOILR}_{t-i} + \sum_{i=1}^{r} \beta_{3i} \Delta \text{LTEX}_{t-i} \]

\[ + \lambda_3 \text{ECT}_{t-1} + \mu_{3t} \]  

(3)

Where ECT is expressed as follows:

\[ \text{ECT}_t = \text{LGDP}_{t-1} - \beta_0 - \beta_1 \text{LOILR}_{t-1} - \beta_2 \text{LTEX}_{t-1}, \]  

(4)

where \( t = 1...T \) denotes the time period.

A major advantage of VECM is that it can also be used to verify causality among the variables in case of cointegrated series. According to Fasano and Wang (2001), the VECM helps distinguish between short-run dynamic among the variable (or short-run causality), and each variable's gradual correction from the long-run equilibrium through a series of partial short-run adjustments (or long-run causality). Therefore, a vector Error Correction model can offer a greater appreciating of the nature of non-stationarity among different variables’ time series. Further, it can also increase longer term forecasting over an unconstrained model (Engle and Yoo (1987), Reinsel and Ahn (1992) and Lin and Tsay (1996)).

4. Empirical results

4.1. Unit root tests

We use the Augmented Dickey–Fuller (F-ADF) unit root tests to test the non-stationarity in our data series (Dickey and Fuller, 1981). Considering the low power of the ADF test we also use the Phillips-Perron (PP) test (1988), as an alternative test, which takes account of the serial correlation and heteroscedasticity. The results are displayed in Table 1.

The test statistics for the log levels of GDP (LGDP), oil revenues (LOILR) and total expenditures (LTEX) are statistically insignificant. When we apply the unit root tests to the first difference of the two variables, both tests reject the joint null hypothesis for each variable.

at the 1% level. Thus, from all of the tests, the unit root tests indicate that each variable is integrated of order one.

After checking the integration of our four variables at order one, i.e., (1), we selected the optimal lag length of underlying Vector Auto Regression (VAR henceforth) using the conventional model selection criteria. These criteria established that the optimal lag length is two.

### 4.2. Cointegration: long-run and short-run

The cointegration tests based on multivariate Johansen approach (1988) uses two statistical tests namely; Trace test and Max-Eigen value. The likelihood ratio (LR) test is based on the trace statistics \(\lambda_\text{trace}(r)\) that tests the null-hypothesis \(H_0: r \leq q\) against \(H_1: q = r\) is calculated thus:

\[
\lambda_\text{trace}(r) = -T \sum_{i=1}^{r} \ln(1-\lambda_i),
\]

where \(\lambda_i\) are the least value of eigenvalues \(p-r\). The second test is the maximal eigenvalue test \(\lambda_\text{max}\). For tests that the null-hypothesis states that there are \(r\) cointegrating vectors against the null: there are \(r+1\) cointegrating vectors and is calculated as follows:

\[
\lambda_\text{max}(r, r+1) = -T \ln\left(1 - \lambda r + 1\right).
\]

The results of the Johansen cointegration tests are displayed in Table 2 below. The Trace test and Max-Eigen value suggest the existence of one cointegrating vector at 1% of significance.

The existence of cointegration signifies that there is at least one long-run equilibrium relationship among the variables. In this case, Granger causality exists among these variables in at least one way (Engle and Yoo, 1987). The VECM is used to correct the disequilibrium in the cointegration relationship and to test for long and short-run causality among cointegrated variables. The correction of the disequilibrium is done by the mean of the Error Correction Term (ECT).

The results of the long-run equilibrium relationship are presented in Table 3 below. It shows that the coefficient of LOILR is 0.263 which is positive and significant at the level of 10%. Moreover, the table reveals that LTEX is also positively associated to GDP and is significant at a level of 1%. This conclusion shows that the government of Bahrain adopts the spend-and-tax hypothesis as suggested by Peacock and Wiseman (1961, 1979) and Barro (1974). This means that changes in expenditures induce changes in revenue. This is evident due to the continuous effort of the government to diversify the economy and to diminish its dependency to oil and energy sector. Nowadays, the small kingdom is becoming a hub of finance, especially for Islamic finance, and a center for business and economic affairs. Therefore, the financial sector contributes significantly in overall GDP as well as in tourism and manufactory.

We now turn to short-run results which are presented in Table 4. Since the objective of the study is to investigate the dynamic relationships between oil revenues, government expenditures and economic growth, Table 4 illustrates the results only in which LGDP is the dependent variable. Since the optimal lag length was two, the short-run results are also presented for two lags of each variable. The results reveal that oil revenues respond negatively and significantly to GDP at the level of 10% of significance.

For the consistency of the analysis, we performed several diagnostic and stability tests to the ECM model. The results are reported in the lower part of Table 4. They confirm the absence of serial correlation (Breusch–Godfrey Serial Correlation LM Test), heteroskedasticity (White Test) and autoregressive conditional heteroskedasticity (ARCH) in the model. The underlying model also passes the diagnostic test for normality (Jacque–Bera).

After discussing long-and short-run dynamics, the next task is to examine the direction of causality between these variables. The results of causality tests based on the VECM model are reported in Table 5 in which we have performed three Granger causality tests: short-run causality long-run causality and the joint short and long run. The first test indicates the significance of the sum of lagged terms of each explanatory variable by the mean of joint Fisher test; the second test indicates the significance of the error correction term by the mean of the t-test and finally the third test is the short-run adjustment to restore the long-run equilibrium.

The F-statistics for short-run significance reveals that oil revenue is the only variable that Granger causes GDP. Thus, we can confirm the presence of a unidirectional relationship running from oil revenues to GDP. Again, this result shows the weight of oil revenues as a principal factor behind the development and the progress of the small kingdom and any positive or negative shock in the oil revenue would quickly impact the economic growth of the kingdom. This result is similar to the one conducted by Eulton and Al-Awadi (2001) in which they found that oil price shocks affect macroeconomic variables in Kuwait. This conclusion also supports the one revealed in Table 4 in which short-run coefficients of LOILR was significant.

The results further show no causality between government expenditures and GDP. This is mainly because expenditures are not invested into productive projects, which could in turn improve the Bahrain’s economic growth significantly. It is worth mentioning that since the past few years, the government of Bahrain has increased

7 Kuwait is an oil-dependent country with approximately the same structure of economy as Bahrain with greater reserves and production of oil.
and has focused its expenditures in improving the infrastructure of the country by building new roads, bridges, schools, hospitals and initially a large program for social housing. Yet we do not see an obvious positive feedback of these projects on the economy and an oil-dependent country, is facing a number of specific challenges, stemming mainly from the fact that oil revenues, which constitute the bulk of government revenues, are exhaustible, volatile, uncertain and largely originate from external demand (Sturm et al., 2001). Therefore, Bahrain is highly exposed to external shocks such as oil shocks. Literature on small states,⁹ suggests that those countries are very vulnerable to external events and face major challenges. They are heavily exposed to the global market behavior and have limited diversification opportunities because of their small domestic markets (World Bank, 2000). Secondly, Bahrain has a limited monetary policy because of the dollar-pegging regime and thus the fiscal multipliers could be weak due to substantial leakages through remittances and imports (Espinoza and Senhadji, 2011). Consequently, to overcome these drawbacks the government of Bahrain should adopt further structural reforms that promote non-oil sector development.

5. Conclusion and policy implications

The 2008 financial turmoil and the ongoing sovereign debt crisis have renewed the debate on the role of fiscal policy in stimulating economic growth and have also raised serious concerns among the policy makers around the world because of its adverse impacts. This is because the effectiveness of fiscal policy is very sensitive to a large set of factors. Further, its role in absorbing shocks relies on the size of fiscal multiplier (Espinoza and Senhadji, 2011). This fact is pertinent for the case of Bahrain as a small state with monetary policy based on the fixed exchange rate. Therefore, this was the motivation of this study. Precisely, we set out to investigate the dynamic relationships between oil revenues, total government expenditures and economic growth in the Kingdom of Bahrain. We used annual time series data from 1960 to 2010 and we performed an econometric model based on the cointegration analysis and error-correction model. The estimations were made to obtain both short and long-run results. The time series diagnostics were investigated before the estimation and the stability tests were conducted to confirm the robustness of results. The Johansen method of cointegration confirmed the existence of a unique long-run relationship among the variables. The long-run results indicate that coefficients of total government expenditures and oil revenues’ variables are statistically significant. The results for short-run, however, show that oil revenue is the only significant variable. The value of the coefficient of the ECT is —0.276 of the GDP which is statistically significant at 5%. This suggests that the convergence is moving fast enough towards the long-run equilibrium. The study also finds uni-directional causalities running from oil revenues to GDP. The results appear robust and might be useful to policy makers for different reasons. Firstly, Bahrain as a small open economy and an oil-dependent country, is facing a number of specific challenges, stemming mainly from the fact that oil revenues, which constitute the bulk of government revenues, are exhaustible, volatile, uncertain and largely originate from external demand (Sturm et al., 2009). Therefore, Bahrain is highly exposed to external shocks such as oil shocks. Literature on small states,⁹ suggests that those countries are very vulnerable to external events and face major challenges. They are heavily exposed to the global market behavior and have limited diversification opportunities because of their small domestic markets (World Bank, 2000). Secondly, Bahrain has a limited monetary policy because of the dollar-pegging regime and thus the fiscal multipliers could be weak due to substantial leakages through remittances and imports (Espinoza and Senhadji, 2011). Consequently, to overcome these drawbacks the government of Bahrain should adopt further structural reforms that promote non-oil sector development.

The impulse response functions (IRFs) is presented in Fig. 2. The chart illustrates the response of each variable of the VAR and the impact of other variables. It shows that the response of GDP to oil revenues is negative for the initial three years and reaches at its peak in the 3rd year and became positive afterward. Furthermore, the response of total government expenditures to oil revenues is positive during the first three years and then it decreases progressively. Overall, from Fig. 2, we conclude that the responses are not considerable and the short run equilibrium adjustment process is fairly fast. The recent volatility in oil prices has slowed the pace of growth of all oil exporting countries, but it did not impact substantially the economy of the small kingdom.

8 We recall that Bahrain did not experience recession with average GDP growth of 4.9% between 2007 and 2011 (Hamdi and Shia, 2012).

independently from government spending.\textsuperscript{10} The government would need to continue its structural adjustment efforts to encourage diversification of the economy,\textsuperscript{11} to broaden and deepen the financial market and to improve the effectiveness of the public sector. It is well-known that Bahrain is the most diversified economy in the GCC region. However, as oil is an exhaustible natural resource, further diversification of the economy appears to be a must. This would reduce the sudden shock in oil prices and would make the economy less reliant on energy resources. Here, the government has to strengthen its efforts in encouraging the development of the private sector by ensuring proper environment and adequate fiscal policies.

The Gulf Cooperation Countries’ common plan to implement a large tax system could be a good instrument to reduce the effect of oil price volatility. Further work is needed in terms of automatic stabilizers.

\textbf{References}

\textsuperscript{10} It is also worth noting that the Bahraini government is attempting to restrain the impact of sudden changes in oil prices and revenues by intensifying the role of the private sector in the economy and maintaining adequate fiscal policies.

\textsuperscript{11} There are no doubts that the increase of the oil prices recorded in recent years has allowed the government to use oil windfalls to modernize infrastructure, create employment and improve social indicators and helped the government to accumulate official reserves and maintain relatively low levels of external debt.
